Occlusion Sensitivity

Probe the trained network from the outside: hide one patch at a time and watch what happens to the score.

① patch covers the object

CNN →

score 0.92 → 0.31

Large drop ⇒ the model was relying on this region.

② patch covers the background

CNN →

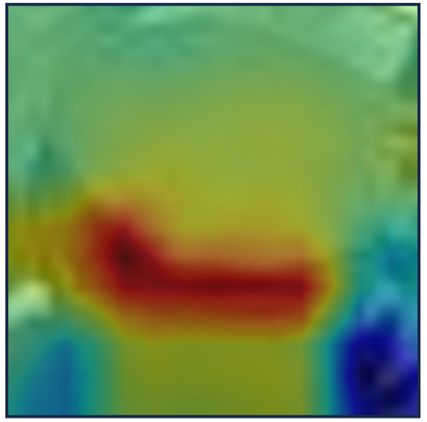

score 0.92 → 0.90

Almost no change ⇒ the model largely ignored this region.

(scores shown are illustrative)

Repeat for every patch position
32×32 patch, stride 16
→ 225 forward passes per image

occlusion sensitivity map

red = covering it hurt the score

Strictly local: each measurement removes exactly one small region, so redundant background elsewhere in the frame stays intact.
